# Whoami

## Education

- Assistant Professor @ TAMU (Since 2022)
- CS PhD @ UFPR, Brazil (2021)
- CSE/ECE BSc. + CS MSC @ UNICAMP, Brazil (2015, 2017)

## Research

- **Malware** at high-level: ML-based detectors.
- **Malware** at mid-level: Sandboxes and tracers.
- **Malware** at low-level: HW-based detectors.

## Current Project

- NSF SaTC: Hardware Performance Counters as the next-gen AVs.

    - Closing Remarks

The trend is in the data

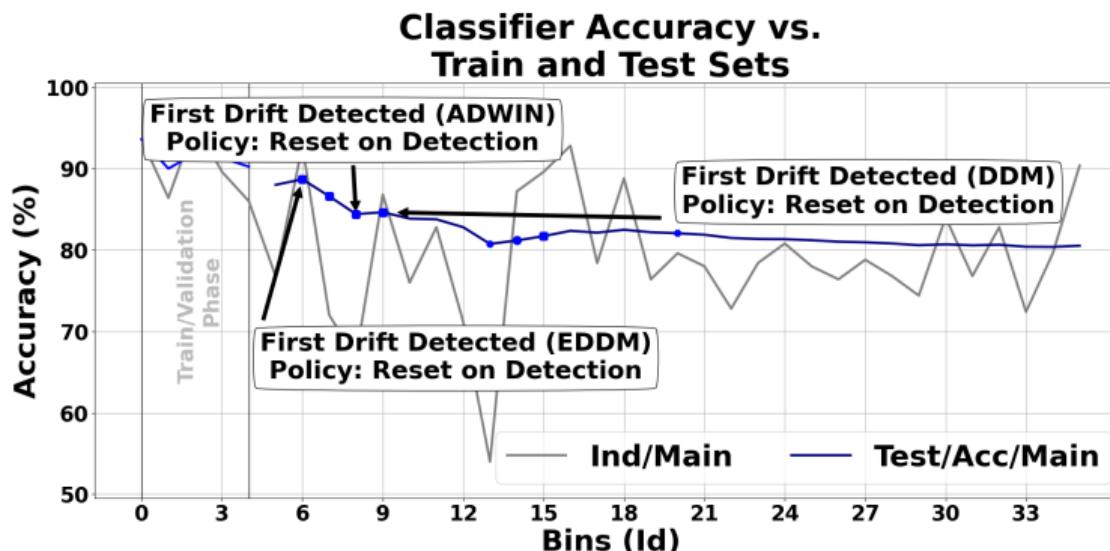

You increase the training size, but the drift is always there!

**Figure: Concept drift in practice.** The classification accuracy decreases regardless of the initial training set size/period.

The trend is in the data

## You change the policy, but the drift is always there!

**Figure: Comparing algorithms and policies.** Each one detects a different number of drift points/events and at different times.

Our theory of drift events

## Proposing a drift taxonomy (1/2)

- **Type 1:** Main Classifier Drift. It detects whether a significant number of samples of any class crossed the detection frontier or not within a sampling window to the point of already harming the final classification result.
- **Type 2:** Sub-Class Drift. It detects whether a significant number of samples of a specific class crossed the detection frontier or not within a sampling window to the point of being noticeable but without guarantees that it affects the final classification result (contingent upon Type 1 detection).
- **Type 3:** Concept Change. It detects if a significant number of samples of a specific class do not match the previous knowledge the classifier had about that class, regardless of the correct class assignment (Type 1 and 2 events).

Our theory of drift events

# The concept evolution direction matters

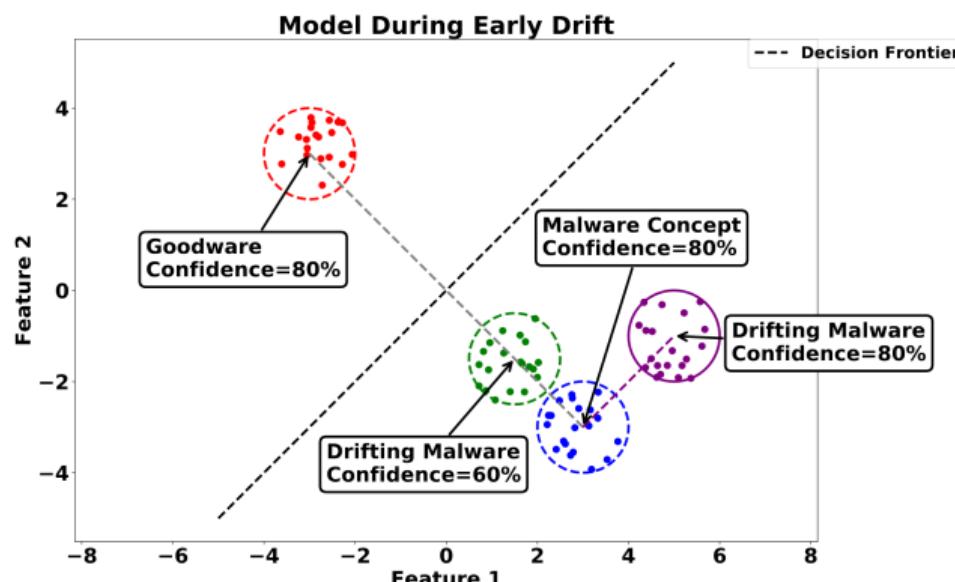

Figure: Direction-Change Drift Detection.

Our theory of drift events

## Proposing a drift taxonomy (2/2)

- **Type 3: Concept Change.** It detects if a significant number of samples of a specific class do not match the previous knowledge the classifier had about that class, regardless of the correct class assignment (Type 1 and 2 events). The implications of the concept change causing drift or not are contingent on the following cases:
  - **Case A:** Concept change without drift risk. If the concept changes in a direction that does not go toward the decision frontier, it cannot cause drift events.
  - **Case B:** Concept change with imminent drift risk. If the concept changes towards the decision frontier (Type 2), it will eventually cause drift when crossing the frontier (Type 1). This point is a candidate for early retraining.
  - **Case C:** Current Drift due to concept change. If the concept changes towards the frontier (Type 2) and crosses it (Type 1), concept drift is detected late.

Our theory of drift events

## The final drift taxonomy

**Table: Explaining Drift Events.** Information types for each combination of triggered detectors. Representing Triggered Detectors (✓) and Possible (△) and Not-Applicable (Ø) cases. Omitting Impossible cases.

Type 1	Type 2	Type 3	Cases			Conclusion
			Case A	Case B	Case C	
			Ø			Normal Operation
	✓	△				Early Concept Change with no impact on frontier
	✓		△			Early Concept Change with imminent impact on frontier
✓			Ø			Bad Frontier detected without concept change hold by imbalance in main class
✓	✓		△			Bad Frontier detected with concept change hold by imbalance in main class
✓			Ø			False Positive Drift Detection
✓	✓	△				False Positive with concept change in non-impactful direction
✓	✓		Ø			Bad Frontier detected without concept change, with impact in the main class
✓	✓	✓		△		Concept Change with Immediate Impact and Identification

The results do make sense

## The concept classes indeed measure different things

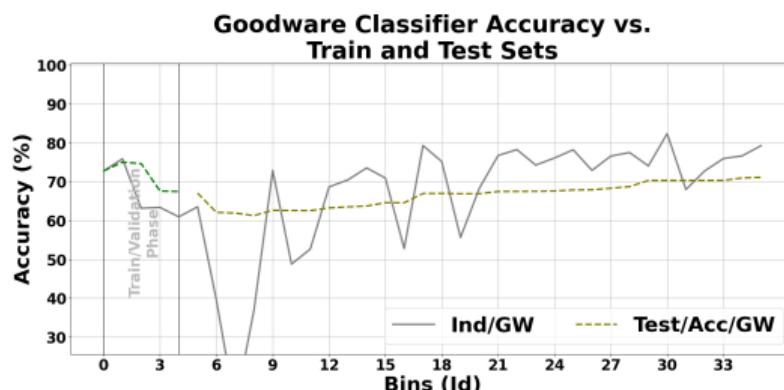

Figure: GW class self-recognition rate.

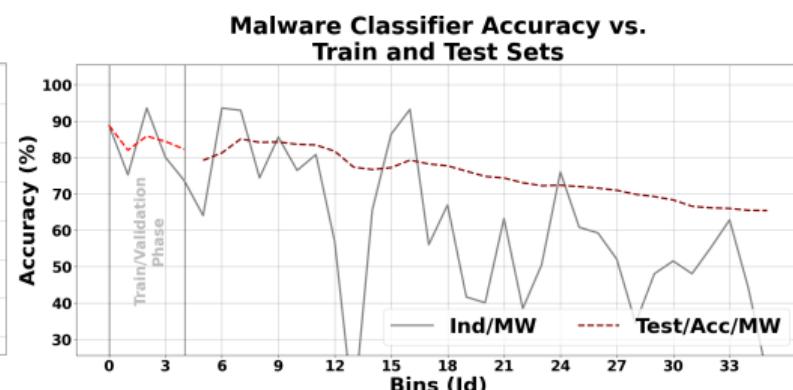

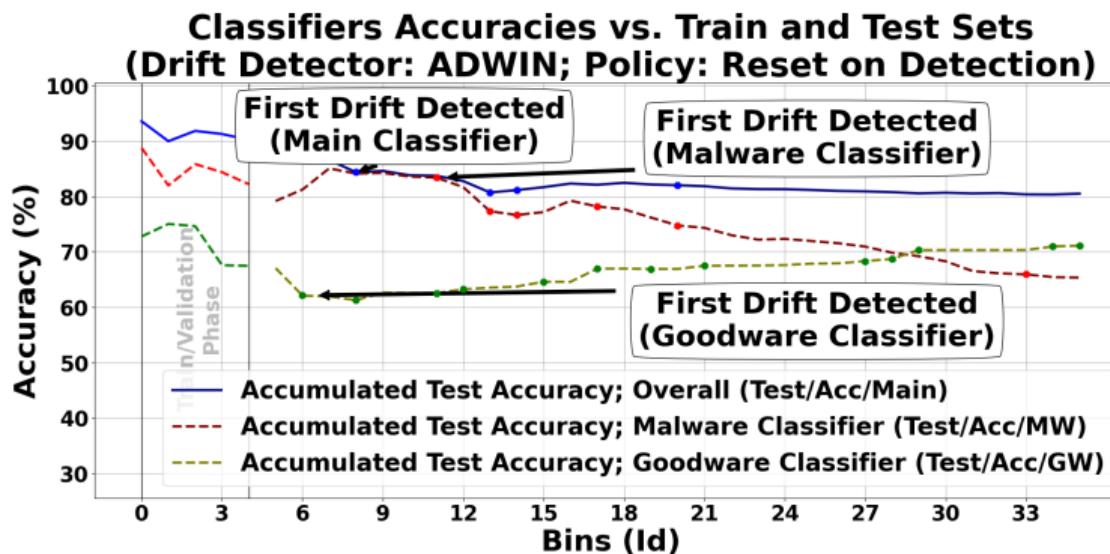

Figure: MW class self-recognition rate.

The results do make sense

## The concept classes indeed drift

**Figure: Drift in the classes self-recognition rates.** Drifts are represented both for the MW and GW meta-classifiers.

Explaining events by examples

# Agenda

## 1 Concept Drift

- It is a long-term trend
- The trend is in the data

## 2 Understanding Drift

- Classes are affected differently
- Our theory of drift events

## 3 Testing the Hypothesis

- How to monitor drift events
- The results do make sense

## 4 Demonstration

- Explaining events by examples
- Generalization

## 5 Real-World Considerations

- Performance Drawbacks
- Labeling Issues

## 6 Engineering Solutions

## 7 Conclusions

- Closing Remarks

Explaining events by examples

Every point can be explained.

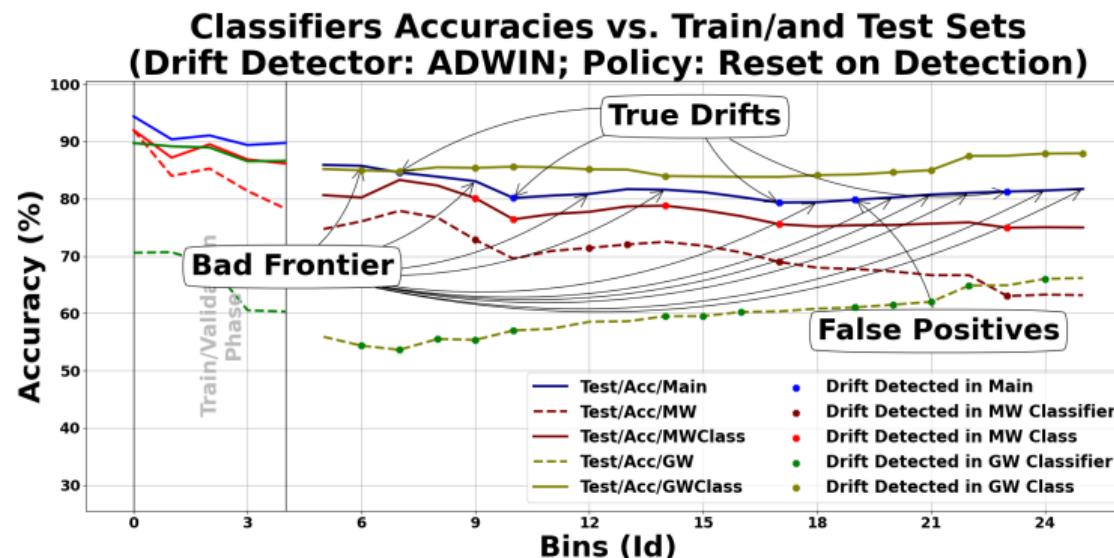

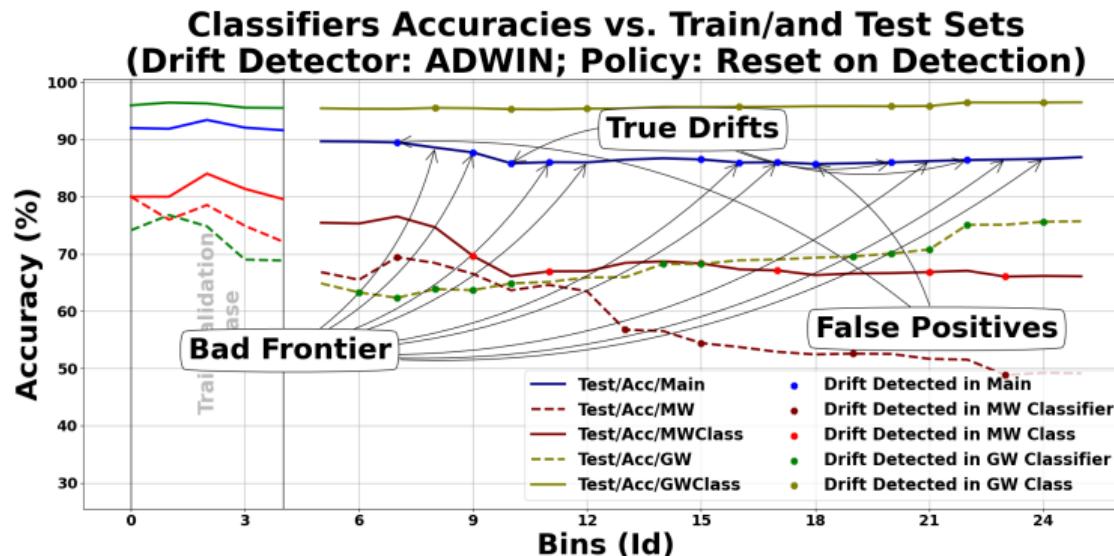

Figure: Explaining all operational points and all drift occurrences. Omitting points of normal operation.

Explaining events by examples

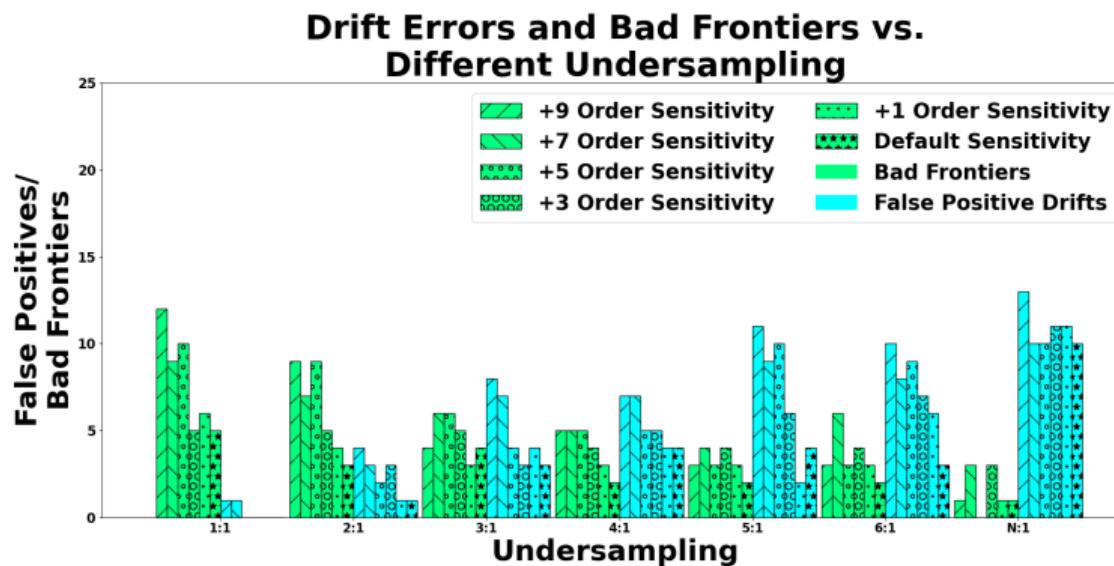

The effect of dataset imbalance is also explained.

**Figure: Explaining all drift detection points (2:1 balance).** We observe fewer frontier problems and more False Positives.

Explaining events by examples

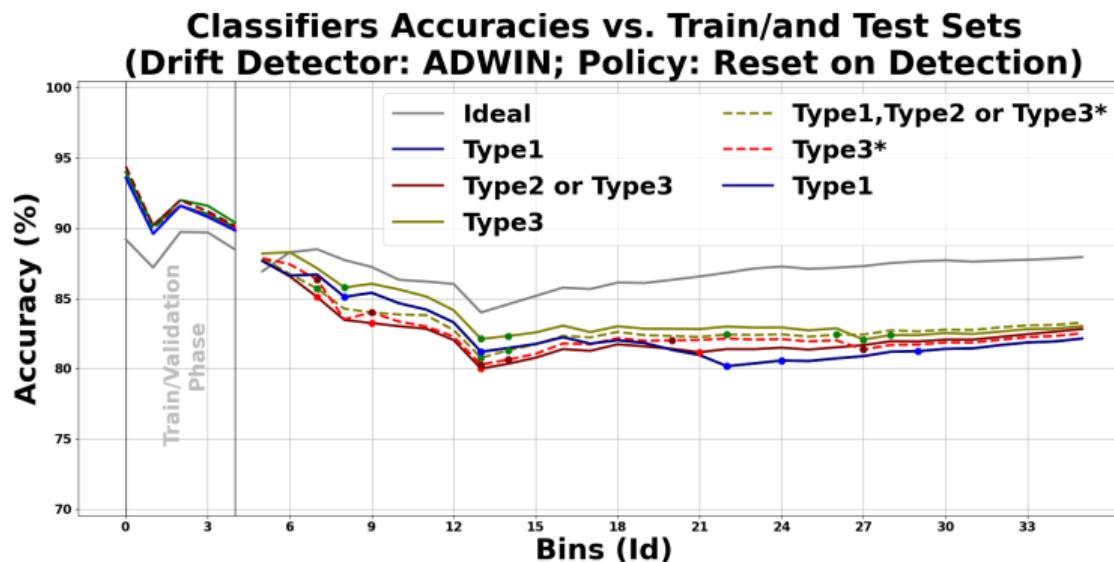

## Calibrating drift detectors is essential

**Figure: Drift Detector Calibration.** False Positives and bad frontiers are explained by the proposed approach.

Explaining events by examples

## Explaining concepts lead to better accuracies via early retrain

**Figure: Early retraining on concept changes leads to improved accuracy than retraining only upon main class drift.**

Explaining events by examples

## Early retrain is more effective

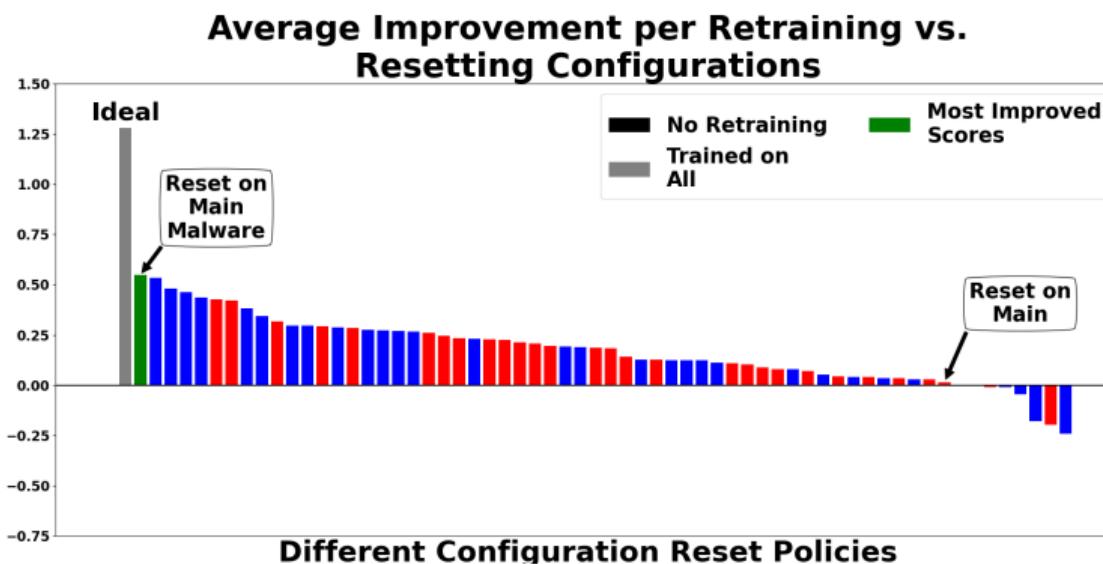

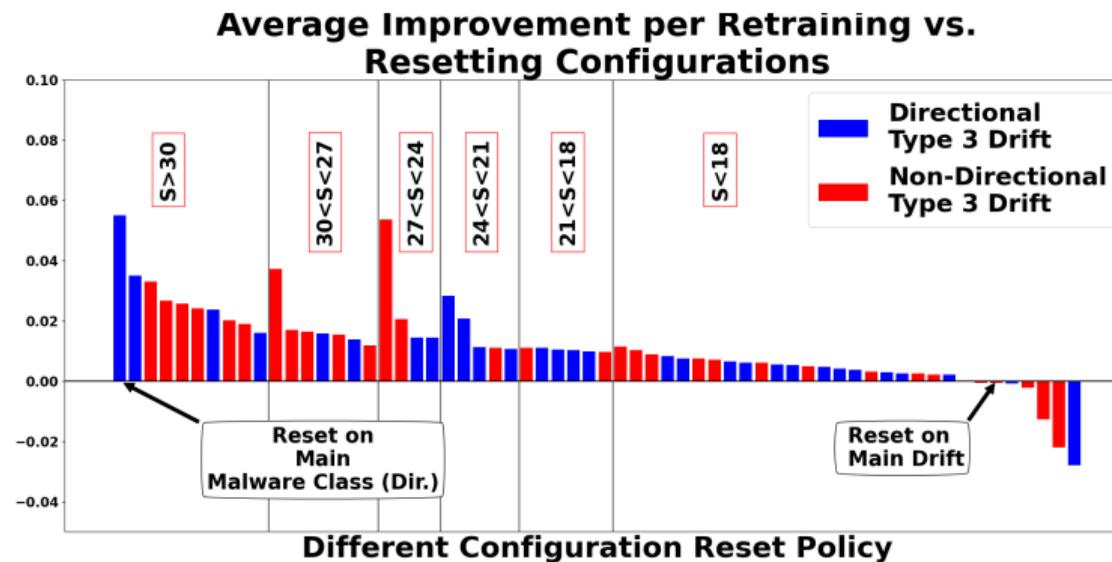

Figure: **Retrain Effectiveness.** The vast majority of the proposed drift detection triggers lead to increased accuracy gains than the original Type 1 drift detector trigger.

Explaining events by examples

## Early retrain is more efficient

**Figure: Retrain Efficiency.** The best cost-benefit between the amount of retrains and accuracy increase is achieved by identifying concept changes.

## Generalization

# Agenda

### 1 Concept Drift

- It is a long-term trend
- The trend is in the data

### 2 Understanding Drift

- Classes are affected differently
- Our theory of drift events

### 3 Testing the Hypothesis

- How to monitor drift events
- The results do make sense

### 4 Demonstration

- Explaining events by examples
- Generalization

### 5 Real-World Considerations

- Performance Drawbacks
- Labeling Issues

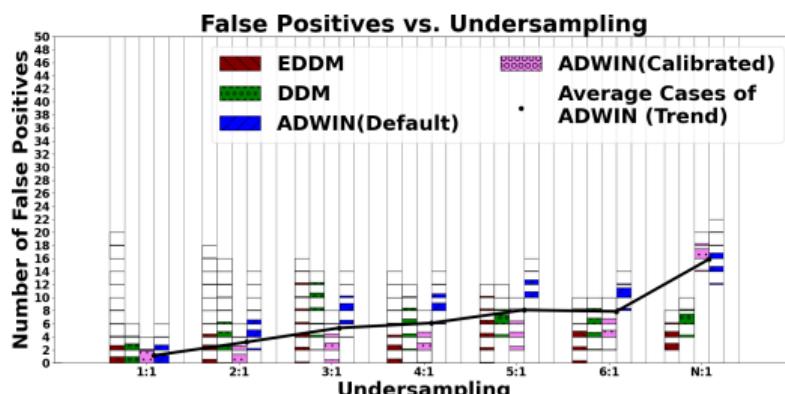

### 6 Engineering Solutions

### 7 Conclusions

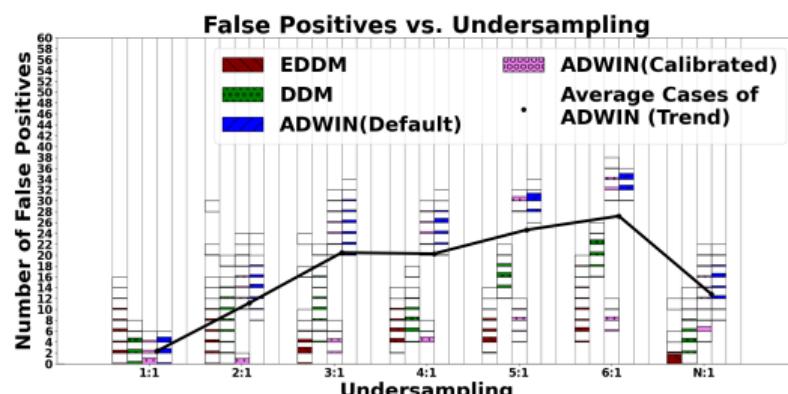

- Closing Remarks

## Generalization

# False Positives always increase with imbalances

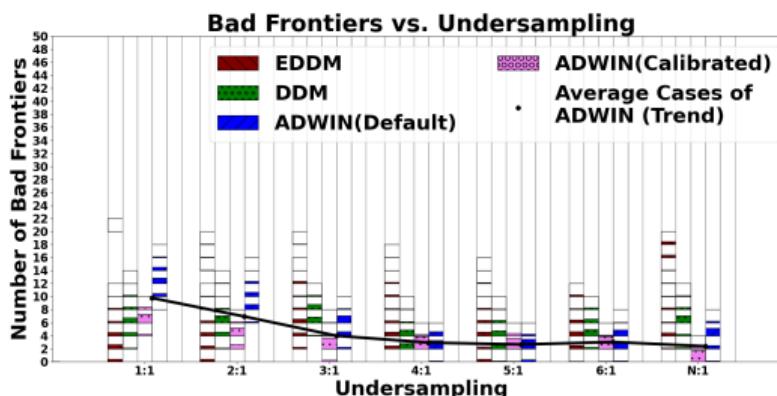

**Figure: DREBIN: FP Results Distribution for different imbalances.** FPs grow with the imbalance for most detectors.

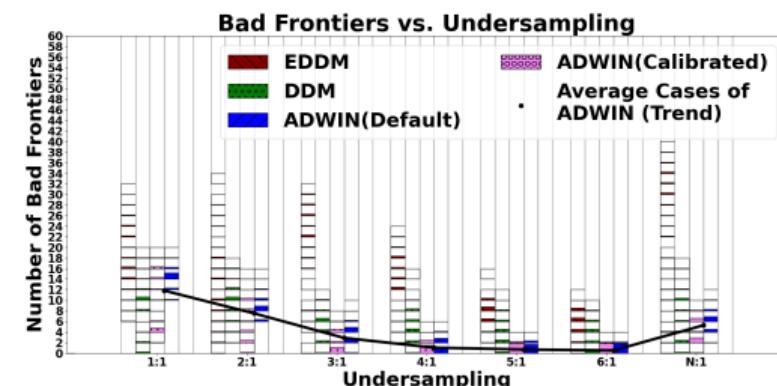

**Figure: ANDROZOO: FP Results Distribution for different imbalances.** FPs grow with the imbalance for most detectors.

# Bad Frontiers always decrease with imbalances

**Figure: DREBIN: Detectors' Results**

**Distribution.** Frontier problems for different undersamplings. The bigger the undersampling, the more frontier problems.

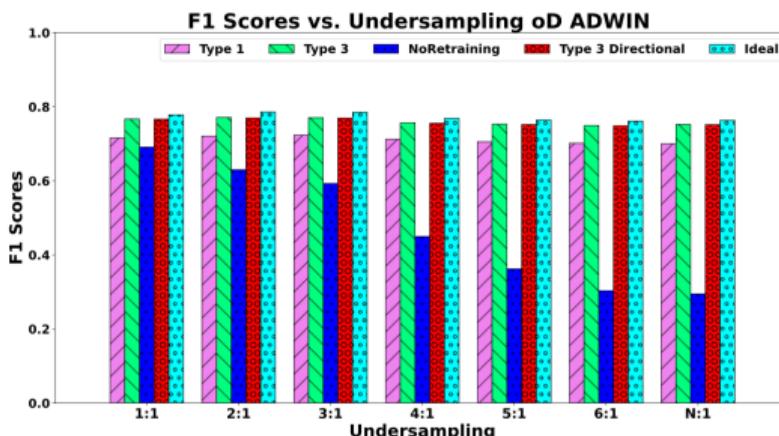

**Figure: ANDROZOO: Detectors' Results**

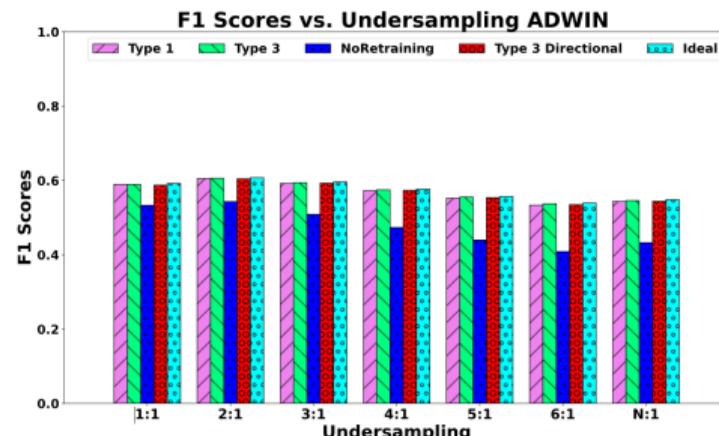

**Distribution.** Frontier problems for different undersamplings. The bigger the undersampling, the more frontier problems.

## Generalization

# Early retrain is always the best option

**Figure: DREBIN: Average Retraining Results.** Average F1-score Under Time increase over the baseline when triggering retrains using different policies vs. the multiple dataset imbalances.

**Figure: ANDROZOO: Average Retraining Results.** The imbalance effect is less pronounced in this dataset, but the Type-3 retraining strategy is still the superior one in all scenarios.

## Performance Drawbacks

# Explanation comes at the performance cost

**Table: Runtime Performance Overhead for DREBIN and AndroZoo.** The cost of individual retrains is reduced, but the total execution time cost increases.

Models (#)	DREBIN			AndroZoo		
	Retrain Policy	Total Time / Retrains (#)	Cost / Overhead / Normalized	Total Time / Retrains (#)	Cost / Overhead / Normalized	
1	Type 1	11.65s / 5	2.73s / 0x / 0x	470.4s / 5	94s / 0x / 0x	
3	Type 1	53.53s / 5	10.7s / 3.92x / 3.92x	1688.6 / 5	337.7s / 3.6x / 3.6x	
3	Type 2	105.77s / 13	8.13s / 7.74x / 2.98x	3563.9s / 15	237.6s / 7.5x / 2.5x	
3	Type 3	102.70s / 13	7.90s / 7.52x / 2.89x	4161.3s / 19	219s / 8.84x / 2.32x	

**Labeling Issues**

# Agenda

**1 Concept Drift**

- It is a long-term trend
- The trend is in the data

# Recap

## Science

- Explaining drift is not the same as explaining the classification.
- Classifier concept and frontier are not the same thing.
- Meta-classifiers can separate concepts and frontiers.
- We can explain every drift event.

## Engineering

- Labels are not immediately available.
- Too long delays eliminate the benefits of classifier retrain.
- Pseudo-Labels mitigate label delays.
